Lasalocid sodium

Lasalocid is a polyether antibiotic obtained by the incubation of *Streptomyces lasaliensis* and has the chemical structure shown above. The one used as a feed additive is its sodium salt (LS). The difference between LS and the other polyether antibiotics (SL, SD, NR and MN) is that LS 1) has a benzene ring in its chemical structure, 2) emits fluorescence, and 3) is negative in chromogenic reaction with vanillin.

For physicochemical properties, LS technical occurs as a white to brownish white powder with a characteristic odor. It is slightly soluble in acetone, in ethanol, in chloroform, in ethyl acetate, and in methanol, and practically insoluble in water.

LS (excluding formulations with lasalocid content not more than 2%) is designated as deleterious substance under the Cabinet Order for the Designation of the Poisonous and Deleterious Substances (Cabnet Order No.2, 1965). For the handing of this substance, make sure to conform to the procedures specified in the Poisonous and Deleterious Substances Control Act (Act No.303, 1950).

LS has an antibacterial effect on part of the Gram-positive bacteria and a coccidial effect. It promotes growth of chickens (including broilers) and improves feed efficiency in fattening cattle.

**Standards and specifications in the Act on Safety Assurance and Quality Improvement of Feeds**

LS is a pure-grade antibiotic that was designated as a feed additive as of July 6, 1983. The specifications for feeds containing this ingredient are specified in Appended Table 1, 1-C of the Ministerial Ordinance Concerning the Ingredient Specifications for Feeds and Feed Additives.

<td>75</td>
<td>33</td>
</tr>
</tbody>
</table>

(in g (potency/t))
The amount of LS added to a commercial premix is roughly 15 to 60 g (potency)/kg. As excessive consumption of LS can cause growth disturbance in chickens and cattle, it is necessary to strictly conform to the added amount specified in the above table and achieve homogeneous mixture to secure safety.

For this reason, feed manufacturers are required to control the feeds containing LS according to the separately specified control test methods (for chicken feed (58 Chiku B No.1676, notified by the Head of the Livestock Industry Bureau, Ministry of Agriculture, Forestry and Fisheries, as of July 6, 1983), chicken feed and cattle feed (3 Chiku B No.1113, notified by the Head of the Livestock Industry Bureau and Head of the Fisheries Agency, the Ministry of Agriculture, Forestry and Fisheries, as of June 3, 1991), and for feed other than powder feed for chickens (6 Chiku B No.1012, notified by the Head of the Livestock Industry Bureau, Ministry of Agriculture, Forestry and Fisheries, as of July 18, 1994)).

[Methods listed in the Feed Analysis Standards]

1  Quantitative test method - Plate method

1.1  Premix

[Feed Analysis Standards, Chapter 9, Section 2, 28.1.1]

A. Reagent preparation

1) Dilution solvent: A mixture of water and methanol (3:1)
2) Lasalocid standard solution. Weigh accurately not less than 40 mg of lasalocid working standard[1], accurately add methanol and dissolve to prepare a lasalocid standard stock solution with a concentration of 1 mg (potency)/mL[2].

At the time of use, accurately dilute a quantity of the standard stock solution with the dilution solvent to prepare high- and low-concentration standard solutions with concentrations of 4 and 1 µg (potency)/mL, respectively[3].
3) Culture medium: Medium F-18
4) Spore suspension and amount of addition. Use Bacillus subtilis ATCC 6633 as the test organism. Add about 0.1 mL of the spore suspension with a concentration of 1×10⁹ spores/mL per 100 mL of the culture medium.
5) Agar plate. Proceed by the agar well method.

B. Preparation of sample solution

Weigh accurately 3 to 5 g of the analysis sample, place in a 200-mL stoppered Erlenmeyer flask, add 100 mL of methanol, extract with stirring for 20 minutes, and filter the extract through filter paper (No.5A).

Accurately dilute a quantity of the filtrate with the dilution solvent to prepare high- and low-concentration sample solutions with concentrations of 4 and 1 µg (potency)/mL, respectively[4].

C. Quantification[5]

Proceed by the 2-2 dose method[6].
**Summary of analysis method**

This method is intended to determine the amount of LS in a premix by microbiological assay using a sample solution prepared by extracting with methanol and diluting with a mixture of water and methanol (3:1). None of the antibacterial substances approved for combined use with LS interfere with the quantification of LS.

The flow sheet of this method is shown in Figure 9.2.28-1.

- Sample (3.0-5.0 g)
- Extract with 100 mL of methanol (with a magnetic stirrer for 20 min).
- Filter (through filter paper No.5A).
- Dilute a quantity of the filtrate with water-methanol (3:1) to prepare high- and low-concentration sample solutions (4 and 1 µg (potency)/mL, respectively).
- Dispense to agar plates (allow to stand at 10-20°C for 2 hr).
- Incubate (at 35-37°C for 16-24 hr).
- Measure the inhibition zone diameter.
- Calculate the potency by the 2-2 dose method.

**Notes and precautions**

[1] For the definition etc. of lasalocid working standard, refer to «Notes and precautions» [9] in Section 1, 1 of this Chapter.

Method of preparation: Example (when the weighed amount is 50 mg)

When the labeled potency of the working standard is 1,022 µg (potency)/mg, 50 mg of the
working standard contains 51,100 µg (potency) (i.e., 50 mg \times 1,022 \, \text{µg (potency)}/\text{mg}). To prepare a standard stock solution with a concentration of 1,000 µg (potency)/mL, the required amount of solvent is thus calculated to be 51.1 mL (i.e., 51,100 µg (potency) / 1,000 µg (potency)/mL). Therefore, completely transfer 50 mg of the working standard to an Erlenmeyer flask containing 51.1 mL of methanol and dissolve to prepare the standard stock solution with a concentration of 1,000 µg (potency)/mL.

An example method of preparation for lasalocid standard solution is shown in Table 9.2.28-1.

[4] For the method of preparation for the sample solution, refer to «Notes and precautions» [8] in Section 1, 1 of this Chapter.

An example method of preparation is shown in Table 9.2.28-1.

[6] Refer to «Notes and precautions» [53] to [60] in Section 1, 1 of this Chapter.

1.2 Chiken feed

[Feed Analysis Standards, Chapter 9, Section 2, 28.2.1]

Scope of application: Chicken feed

A. Reagent preparation

1) Lasalocid standard solution. Weigh accurately not less than 40 mg of lasalocid working standard, accurately add methanol and dissolve to prepare a lasalocid standard stock solution with a concentration of 1 mg (potency)/mL.

At the time of use, accurately dilute a quantity of standard stock solution with a mixture of water and methanol (3:1) to prepare high- and low-concentration standard solutions with concentrations of 1 and 0.5 µg (potency)/mL, respectively.[1]

2) Culture medium: Medium F-18

3) Spore suspension and amount of addition. Use Bacillus subtilis ATCC 6633 as the test organism. Add about 0.4 mL of 1×10^7 spores/mL per 100 mL of the culture medium.

4) Agar plate. Proceed by the agar well method.

5) Silica gel. Dry silica gel for column chromatographyNote 1 (particle size: 63 to 200 µm (230 to 70mesh)) at 110°C for 2 hours.

B. Preparation of sample solution

Extraction. Weigh accurately a quantity of the analysis sample (equivalent to 1 mg (potency) as LS)[2], place in a 200-mL stoppered Erlenmeyer flask, add 100 mL of chloroform, extract with stirring for 20 minutes, and filter the extract through filter paper (No.5A). Transfer 25 mL of the filtrate to a 50-mL stoppered test tube, dehydrate with sodium sulfate (anhydrous), filter through filter paper (No.5A), and use the filtrate as the sample solution subject to column treatment.

Column treatment. Suspend 2.5 g of silica gel in methanol, pour into a column tube (10 mm in internal diameter), and wash with 20 mL of methanol and 50 mL of chloroform in this order to prepare the column.

Load accurately 5 mL of the sample solution onto the column, allow to flow out at a rate of 2 to 3 mL/min until the liquid level is 3 mm above the top of the packing material, and add 30 mL of chloroform and allow to flow out in the same manner.[3]

Place a 50-mL recovery flask under the column, add 15 mL methanol to the column to elute LS, evaporate the eluate into dryness under reduced pressure in a water bath at 50°C, and add accurately 5 mL methanol to dissolve the residue. Accurately dilute a quantity of this solution with a mixture of water and methanol (5:1) to prepare a high-concentration sample solution with a concentration of 1 µg (potency)/mL.[4] Further, accurately dilute this solution with a mixture of water and methanol (3:1) to prepare a low-concentration sample solution with a concentration of 0.5 µg (potency)/mL.[5]

C. Quantification[6]

Proceed by the 2-2 dose method[7].
**Summary of analysis method**

This method is intended to determine the amount of LS in a chicken feed by microbiological assay using a sample solution prepared by extracting with chloroform, adsorbing to a silica gel column, and removing fat and oil. None of the antibacterial substances approved for combined use with LS interfere with the quantification of LS.

The flow sheet of this method is shown in Figure 9.2.28-5.

1.3 Cattle feed

Scope of application: Cattle feed

**A. Reagent preparation**

1) Lasalocid standard solution. Weigh accurately not less than 40 mg of lasalocid working standard, accurately add methanol and dissolve to prepare a lasalocid standard stock solution with a concentration of 1 mg (potency)/mL.

   At the time of use, accurately dilute a quantity of the standard stock solution with a mixture of water and methanol (3:1) to prepare high- and low-concentration standard solutions with concentrations of 2 and 1 µg (potency)/mL, respectively[1].

2) Culture medium: Medium F-18

3) Spore suspension and amount of addition. Use *Bacillus subtilis* ATCC 6633 as the test organism. Add about 0.4 mL of the spore suspension with a concentration of $1 \times 10^7$ spores/mL per 100 mL of the culture medium.

4) Agar plate. Proceed by the agar well method.

5) Enzyme solution. Dissolve 4 g of diastase in water to make 100 mL.

**B. Preparation of sample solution**

Extraction. Weigh 18.2 g of the analysis sample, place in a 200-mL stoppered Erlenmeyer flask, add 15 mL of the enzyme solution, stir, and allow to stand for 10 to 20 minutes at room temperature. Further, add 85 mL of acetonitrile, extract with stirring for 30 minutes, filter the extract through filter paper (No.5A), and use the filtrate as a sample solution subject to purification[2].

Purification. Transfer exactly 25 mL of the sample solution to a 200-mL separating funnel, add 25 mL of water[3], further add 50 mL of hexane, shake for 10 minutes, and allow to stand. Transfer the hexane phase (upper phase) to a 200-mL recovery flask. To the residual liquid add 50 mL of hexane, shake for 1...
minutes, and transfer the hexane phase to the recovery flask. Further, to the residual liquid add 50 mL of hexane and proceed in the same manner. Evaporate the hexane phase into dryness under reduced pressure in a water bath at 50°C, add 10 mL of hexane to dissolve the residue, and use as a sample solution subject to column treatment.

Column treatment. Wash a silica gel minicolumn (690 mg) with 10 mL of hexane.

Load the sample solution onto a minicolumn and allow to flow down until the amount in the minicolumn reservoir is 1 mL. Wash the recovery flask that contained the sample solution with 10 mL of hexane, add the washings to the minicolumn, and repeat this procedure 2 times. Then, load 20 mL of hexane and 20 mL of chloroform in this order to wash the minicolumn.

Place a 50-mL recovery flask under the minicolumn, and load 30 mL of a mixture of chloroform and methanol (4:1) onto the minicolumn to elute LS. Evaporate the eluate into dryness under reduced pressure in a water bath at 50°C, add exactly 10 mL of methanol to dissolve the residue, and filter this solution through filter paper (No.5A).

Accurately dilute a quantity of the filtrate with a mixture of water and methanol (45:7) to prepare a high-concentration sample solution with a concentration of 2 µg (potency)/mL. Further, accurately dilute this solution with a mixture of water and methanol (3:1) to prepare a low-concentration sample solution with a concentration of 1 µg (potency)/mL.

C. Quantification

Proceed by the 2-2 dose method.

«Summary of analysis method»

This method is intended to determine the amount of LS in a cattle feed by microbiological assay using a sample solution prepared by extracting with acetonitrile, separating by liquid-liquid partition, and purifying through a silica gel minicolumn.

The flow sheet of this method is shown in Figure 9.2.28·7.
Sample (18.2 g)

Add 15 mL of enzyme solution, stir, and allow to stand for 10-20 min.

Add 85 mL of acetonitrile and stir (with a magnetic stirrer for 30 min).

Filter (through filter paper No.5A).

To 25 mL of the filtrate add 25 mL of water and 50 mL of hexane and (in a 200-mL separating funnel) and shake for 10 min.

Collect the hexane phase (upper phase) (into a 200-mL recovery flask).

To the separating funnel add 50 mL of hexane, shake for 1 min, and transfer to a recovery flask (repeat 2 times).

Evaporate into dryness under reduced pressure (in a water bath at 50°C).

Dissolve the residue with 10 mL of hexane.

Load on a silica gel minicolumn (previously washed with 10 mL of hexane).

Wash the round-bottom flask with 10 mL of hexane and load the washings onto the silica gel minicolumn (repeat 2 times).

Wash the silica gel minicolumn with 20 mL of hexane and 20 mL of chloroform in this order.

Elute LS with 30 mL of chloroform-methanol (4:1) (into a 50-mL recovery flask).

Evaporate into dryness under reduced pressure (in a water bath at 50°C).

Dissolve the residue in 10 mL of methanol.

Filter (through filter paper No.5A).

Dilute a quantity of the filtrate with water-methanol (45:7) to prepare a high-concentration sample solution (2 µg (potency)/mL).

Dilute a quantity of the high-concentration sample solution with water-methanol (3:1) to prepare a low-concentration sample solution (1 µg (potency)/mL).

Dispense to agar plates (allow to stand at 10-20°C for 2 hr).

Incubate (at 35-37°C for 16-24 hr).

Measure the inhibition zone diameter.

Calculate the potency by the 2:2 dose method.

Note: "2 mL" means "2 mL of standard stock solution (1 mg/potency)/mL".

[2] In the case of pellet feed, the constituents can be altered as a result of heat-processing, making it difficult to extract LS with an ordinary solvent. For this reason, this method employs the use of an enzyme for decomposing a substance that can interfere with the extraction of LS with acetonitrile.

[3] The addition of water is intended to facilitate the transfer of LS to the hexane phase during liquid-liquid partition.

[4] An example method of preparation for the high-concentration sample solution is shown below.

- Filtrate 4 mL
- Water-methanol (45:7) 26 mL

[5] An example method of preparation for the low-concentration sample solution is shown below.

*(Bacillus subtilis* ATCC 6633, Medium F-18, Agar well method)*

2.1 Quantitative test method - Liquid chromatography

2.1 Premix

[A. Reagent preparation]

Lasalocid sodium standard solution. Weigh accurately a quantity of lasalocid working standard equivalent to 50 mg (potency), place in a 100-mL volumetric flask, add methanol and dissolve, and further add methanol to the marked line to prepare a lasalocid sodium standard stock solution (1 mL of this solution contains an amount equivalent to 0.5 mg (potency) as lasalocid sodium).

At the time of use, accurately dilute a quantity of the standard stock solution with methanol to prepare several standard solutions containing lasalocid sodium in amounts equivalent to 1 to 15 µg (potency) in 1 mL.

[B. Quantification]

Extraction. Weigh accurately 2 to 5 g of the sample, place in a 200-mL stoppered Erlenmeyer flask, add 100 mL of methanol, and extract with stirring for 30 minutes. Transfer the extract to a 50-mL stoppered centrifuge tube, centrifuge at 1,500×g for 5 minutes, and accurately dilute a quantity of the supernatant liquid with methanol. Further filter this solution through membrane filter (pore size not exceeding 0.5 µm) and use the filtrate as the sample solution subject to liquid chromatography.

Liquid chromatography. Inject 20 µL each of the sample solution and the lasalocid sodium standard solutions into a chromatograph to obtain chromatograms.

Example operating conditions

Detector: Fluorescence detector (excitation wavelength: 310 nm; emission wavelength: 420 nm)

Column: Octadecylsilanized silica gel column (4.6 mm in internal diameter, 250 mm in length, 5 µm in particle size)\(^{Note1}\) [1]

Eluent: A mixture of methanol and phosphoric acid buffer solution\(^{Note2}\) (9:1)

Flow rate: 1.0 mL/min

Column temperature: 40°C

Calculation. Calculate the peak height or peak area from the obtained chromatograms\(^{2}\) to prepare the
calibration curve, and estimate the amount of lasalocid sodium in the sample.

Note 1. Use a Shodex Silica C18M 4E (Showa Denko K.K.) or an equivalent

2. Dissolve 2.72 g of potassium dihydrogen phosphate in water to make 1 L and adjust the pH to
2.9 to 3.1 with phosphoric acid (1:10).

«Summary of analysis method»

This method is intended to determine the amount of LS in a premix by liquid chromatography using a sample solution prepared by extracting with methanol and diluting with methanol.

The flow sheet of this method is shown in Figure 9.2.28-3.

2.0-5.0 g of the sample
- Add 100 mL of methanol and extract with stirring for 30 min.
- Centrifuge (at 1,500×g for 5 min).
- Filter through membrane filter (pore size not exceeding 0.5 µm).
- LC-FL (Ex: 310 nm, Em: 420 nm)

«Notes and precautions»

[1] Any column with an equivalent end-capped packing material is applicable.
[2] An example chromatogram for LS is shown in Figure 9.2.28-4.
### Operating conditions

Detector: Measured wavelength: Em 310 nm; Ex 420 nm  
Column: Shodex C18-5B  
Eluent: A mixture of methanol and phosphoric acid buffer solution (9:1)  
Flow rate: 1.0 mL/min  
Column temperature: 40°C

**Figure 9.2.28-4 Chromatogram for lasalocid sodium added to a chicken premix**  
(The arrow indicates the peak of lasalocid)

### 2.2 Feed

**Scope of application:** Chicken feed

#### A. Reagent preparation

1) Lasalocid sodium standard solution. Weigh accurately a quantity of lasalocid working standard equivalent to 50 mg (potency), place in a 100-mL volumetric flask, add methanol to dissolve, further add ethanol up to the marked line to prepare a lasalocid sodium standard stock solution (1 mL of this solution contains an amount of lasalocid sodium equivalent to 0.5 mg (potency)).  
At the time of use, accurately dilute a quantity of the standard stock solution with methanol to prepare several lasalocid sodium standard solutions containing amounts of lasalocid sodium equivalent to 1 to 15 µg (potency) in 1 mL.

2) Enzyme solution. Dissolve 2.5 g of diastase in water to make 100 mL.

#### B. Quantification

**Extraction**

1) When the analysis sample is a heat-processed feed such as pellets

   Weigh 10.0 g of the analysis sample, place in a 200-mL stoppered Erlenmeyer flask, add 20 mL of the enzyme solution, mix thoroughly\(^{[1]}\), and allow to stand in a water bath at 40°C for 20 minutes. Further, add 80 mL of methanol, and extract with stirring for 10 minutes\(^{[2]}\). Transfer 50 mL of the extract to a centrifuge tube, centrifuge at 1,500×g for 5 minutes, filter the supernatant liquid through membrane filter (pore size not exceeding 0.5 µm), and use the filtrate as a sample solution subject to liquid chromatography.

2) When the analysis sample is a feed other than heat-processed feeds such as pellets

   Weigh 10.0 g of the analysis sample, place in a 200-mL stoppered Erlenmeyer flask, add 100 mL of methanol, and extract with stirring for 30 minutes. Transfer the extract to a 50-mL stoppered centrifuge tube, centrifuge at 1,500×g for 5 minutes, and filter the supernatant liquid through membrane filter (pore size not exceeding 0.5 µm), and use the filtrate as a sample solution subject to liquid chromatography.
Liquid chromatography. Inject 20 µL each of the sample solution and the lasalocid sodium standard solutions into a liquid chromatograph to obtain chromatograms.

Example operating conditions

- Detector: Fluorescence detector (excitation wavelength: 310 nm, emission wavelength: 420 nm)
- Column: Octadecylsilanized silica gel column (4.6 mm in internal diameter, 250 mm in length, 5 µm in particle size)
- Eluent: A mixture of methanol and phosphoric acid buffer solution (9:1)
- Flow rate: 1.0 mL/min
- Column temperature: 40°C

Calculation. Calculate the peak height or peak area from the obtained chromatograms to prepare the calibration curve, and estimate the amount of lasalocid sodium in the sample.

Note 1. Use Shodex Silica C18M 4E (Showa Denko K.K.) or an equivalent.

2. Dissolve 2.72 g of potassium dihydrogen phosphate in water to make 1 L and adjust the pH to 2.9 to 3.1 with phosphoric acid (1:10).

«Summary of analysis method»

This method is intended to determine the amount of LS in a chicken feed by liquid chromatography equipped with a fluorescence detector using a sample solution prepared by extraction and purification. When the analysis sample is a pellet feed, it shall be treated with an enzyme solution and heated before being extracted with methanol. When the analysis sample is a feed other than pellets, it shall be extracted with ethanol.

The flow sheet of this method is shown in Figure 9.2.28-9.

«Notes and precautions»

[2] In case of pellet feed, the constituents can be altered as a result of heat-processing, making it difficult to extract LS with methanol. For this reason, this method employs the use of an enzyme for decomposing a substance that can interfere with the extraction of LS with ethanol.

[3] Any column with an equivalent end-capped packing material is applicable.

[4] An example chromatogram is shown in Figure 9.2.28-10.

3 Trace quantitative test method (feed)
3.1 Trace quantitative test method for polyether antibiotics by microbioautography

[Feed Analysis Standards, Chapter 9, Section 2, 28.3.1]

Antibiotics of interest: SL, MN and LS (3 components)
Scope of application: Feed

A. Reagent preparation

1) Salinomycin standard solution. Dry a suitable amount of salinomycin working standard under reduced pressure (not exceeding 0.67 kPa) at 60°C for 3 hours, weigh accurately not less than 40 mg, add methanol and dissolve to prepare a salinomycin standard stock solution with a concentration of 1 mg (potency)/mL.

At the time of use, accurately dilute a quantity of the standard stock solution with methanol to prepare standard solutions with concentrations of 20, 10, 5, 2.5 and 1.25 µg (potency)/mL[1].

2) Monensin standard solution. Weigh accurately not less than 40 mg of monensin working standard, add methanol and dissolve to prepare a monensin standard stock solution with a concentration of 1 mg (potency)/mL.

At the time of use, accurately dilute a quantity of the standard stock solution with methanol to prepare standard solutions with concentrations of 20, 10, 5, 2.5 and 1.25 µg (potency)/mL[1].

3) Lasalocid standard solution. Weigh accurately not less than 40 mg of lasalocid working standard, add methanol and dissolve to prepare a lasalocid standard stock solution with a concentration of 1 mg (potency)/mL.

At the time of use, accurately dilute a quantity of the standard stock solution with methanol to prepare standard solutions with concentrations of 20, 10, 5, 2.5 and 1.25 µg (potency)/mL[1].

4) Culture medium: Medium F-22

5) Pore suspension and amount of addition. Use Bacillus subtilis ATCC 6633 as the test organism. Add about 0.1 mL of the pore suspension with a concentration of 1×10⁷ spores/mL per 100 mL of the culture medium.

6) Developing solvent[2]
   i) A mixture of ethyl acetate, hexane, acetone and methanol (20:8:1:1)
   ii) A mixture of ethyl acetate and ammonia solution (180:1)

7) Sodium sulfate (anhydrous). Dry at 110 to 120°C for 2 hours and allow to cool in a desiccator.

8) Chromogenic substrate. Dissolve 100 mg of 3·(4-iodophenyl)-2·(4-nitrophenyl)-5-phenyltetrazolium chloride in water to make 200 mL.

B. Preparation of sample solution

Extraction. Weigh 40.0 g of the analysis sample, place in a 200-mL stoppered Erlenmeyer flask, add 100 mL of acetonitrile, extract with stirring for 30 minutes, and filter the
extract through filter paper (No.5A). Transfer 50 mL of the filtrate to a 100-mL recovery flask, evaporate into dryness under reduced pressure in a water bath at 50°C, add 20 mL of a mixture of chloroform and ethyl acetate (9:1) to dissolve the residue, and use as the sample solution subject to column treatment.

Column treatment. Wash a silica gel minicolumn (690 mg) with 10 mL of chloroform.

On the minicolumn place a funnel loaded with approximately 40 g of sodium sulfate (anhydrous)[3], pour the sample solution into the funnel, and allow to flow down until the amount in the minicolumn reservoir reaches 1 mL[4]. Wash the recovery flask that contained the sample solution with 10 mL of a mixture of chloroform and ethyl acetate (9:1), transfer the washings to the funnel, and repeat this procedure 3 times.

Wash the sodium sulfate in the funnel with a mixture of chloroform and ethyl acetate (9:1), transfer the washings to the minicolumn, remove the funnel, and add 20 mL of a mixture of chloroform and ethyl acetate (9:1) to wash the minicolumn.

Place a 50-mL recovery flask under the minicolumn, and add 30 mL of a mixture of chloroform and methanol (4:1) to the minicolumn to elute SL, MN and LS. Evaporate the eluate into dryness under reduced pressure in a water bath at 50°C, accurately add 2 mL of methanol to dissolve the residue[5], and use as the sample solution.

C. Quantification[6]

Proceed as described in Section 1, 2-C[7] except for the following procedures.

Use a thin-layer plate made of silica gel Note 1 and develop until the ascending front of the developing solvent reaches the top of the thin-layer plate.

Note 1. Use a TLC plate Silica gel 60 (20×20 cm) (Merck) or an equivalent after drying at 110°C for 2 hours.

「Summary of analysis method」

This method is intended to quantify and identify SL, MN or LS contamination due to carry-over etc. in a feed by microbioautography using a sample solution prepared by extracting with acetonitrile, purifying through a silica gel minicolumn, and dissolving in methanol.

The flow sheet of this method is shown in Figure 9.3.3-1.
Sample (40.0 g)  
Extract with 100 mL of acetonitrile (with a magnetic stirrer for 30 min).  
Filter (through filter paper No.5A).  
Collect 50 mL of the filtrate (into a 100-mL recovery flask).  
Evaporate into dryness under reduced pressure (in a water bath at 50°C).  
Dissolve the residue with 20 mL of chloroform-ethyl acetate (9:1).  
Load onto a silica gel minicolumn (previously washed with 10 mL of chloroform and equipped on the reservoir with a funnel containing approximately 40 g of sodium sulfate).  
Wash the recovery flask with 10 mL of chloroform-ethyl acetate (9:1) and load the washings onto the silica gel minicolumn (repeat 3 times).  
Wash the sodium sulfate with 10 mL of chloroform-ethyl acetate (9:1) and load the washings onto the silica gel minicolumn.  
Wash the silica gel minicolumn with 20 mL of chloroform-ethyl acetate (9:1).  
Elute SL, MN and LS with 30 mL of chloroform-ethanol (4:1) (into a 50-mL recovery flask).  
Evaporate into dryness under reduced pressure (in a water bath at 50°C).  
Dissolve the residue with 2 mL of methanol.  
Spot on a thin-layer plate (20 µL).  
Develop.  
Prepare agar plates (allow to stand at 10-20°C for 3 hr).  
Incubate (at 35-37°C for 16-24 hr).  
Measure the inhibition zone diameter and determine the Rf value.  
Calculate the potency from the calibration curve.

Note: "2 mL" means "2 mL of standard stock solution (1 mg (potency)/mL).

[2] Usually, proceed only with a mixture of ethyl acetate, hexane, acetone, and methanol (20:8:1:1). When an inhibition zone is observed with the sample solution, perform a re-test with a mixture of ethyl acetate and ammonia solution (180:1) to make a more precise identification.

[3] It is recommended to stuff a small amount of absorbent cotton at the top of the funnel stem on which to place sodium sulfate (anhydrous).

[4] When the flow is slow, it is permissible to inject under pressure using the syringe plunger or a double-balloon pump.

[5] When the residue is difficult to dissolve, apply ultrasonic waves for 2 to 3 minutes.

[6] Example standard response lines for SL, MN and LS are shown in Figure 9.3.3-2 to 4.

3.2 Trace quantitative test method for polyether antibiotics by liquid chromatography mass spectrometry [Feed Analysis Standards, Chapter 9, Section 2, 28.3.2]  
Antibiotics of interest: SL, SD, NR, MN and LS (5 components)
**Scope of application:** Formula feed

**A. Reagent preparation**

1) Standard stock solution of each antibiotic\[^{[1]}\]. Weigh accurately a quantity equivalent to 20 mg (potency) each of salinomycin working standard, narasin working standard, monensin working standard, and lasalocid working standard, place each in a 100-mL volumetric flask, add methanol to dissolve, and further add methanol up to the marked line to prepare respective standard stock solutions (1 mL each of these solutions contains an amount equivalent to 0.2 mg (potency) as salinomycin sodium, semduramicin sodium, narasin, monensin sodium, and lasalocid sodium, respectively).

2) Mixed standard solution. At the time of use, mix quantities of the standard stock solutions of salinomycin sodium, semduramicin sodium, narasin, monensin sodium, and lasalocid sodium. Accurately dilute the mixture with methanol to prepare several mixed standard solutions containing amounts equivalent to 0.1 to 2 µg (potency) as each antibiotic in 1 mL.

**B. Quantification**

Extraction. Weigh 10.0 g of the analysis sample, place in a 200-mL stoppered Erlenmeyer flask, add 100 mL of acetonitrile, extract with stirring for 30 minutes, and filter the extract through filter paper (No.5A). Transfer exactly 25 mL of the filtrate to a 100-mL recovery flask, condense under reduced pressure almost into dryness in a water bath at 40°C, and evaporate into dryness by introducing nitrogen gas.

Add 10 mL of a mixture of hexane and ethyl acetate (9:1) to dissolve the residue, and use as the sample solution subject to column treatment.

Column treatment. Wash a silica gel minicolumn (690 mg) with 10 mL of hexane, and on the minicolumn reservoir place a funnel previously loaded with approximately 20 g of sodium sulfate (anhydrous)\[^{[2]}\].

Pour the sample solution into the funnel, and allow to flow down until the liquid level reaches the top of the column packing material. Wash the recovery flask that contained the sample solution 3 times with 5 mL of a mixture of hexane and ethyl acetate (9:1), transfer the washings each time to the funnel, and allow to flow down in the same manner. Further, wash the sodium sulfate in the funnel with 5 mL of a mixture of hexane and ethyl acetate (9:1), allow to flow down in the same manner, remove the funnel, and add 10 mL of a mixture of hexane and ethyl acetate (9:1) to wash the minicolumn.

Place a 50-mL recovery flask under the minicolumn, and add 15 mL of a mixture of hexane and ethanol (4:1) to the minicolumn to elute each antibiotic. Condense the eluate almost into dryness under reduced pressure in a water bath at 40°C, and evaporate into dryness by introducing nitrogen gas.

Add exactly 10 mL of methanol to dissolve the residue, centrifuge at 5,000×g for 5 minutes, and use the supernatant liquid as the sample solution subject to liquid
chromatography-mass spectrometry. Measurement by liquid chromatography-mass spectrometry. Inject 5 μL each of the sample solution and mixed standard solutions into a liquid chromatograph-mass spectrometer to obtain selected ion detection chromatograms.

Example operating conditions

Column: Octadecylsilanized silica gel column (2 mm in internal diameter, 50 mm in length, 5 μm in particle size)\(^\text{Note 2}\)

Eluent: A mixture of 5 mmol/L ammonium acetate solution and acetonitrile (1:4)

Flow rate: 0.2 mL/min

Column temperature: 40°C

Detector: Quadrupole mass spectrometer\(^\text{Note 3}\)

Ionization method: Electrospray ionization (ESI) (positive ion mode)

Nebulizer gas: N\(_2\) (1.5 L/min)

CDL temperature: 250°C

Heat block temperature: 200°C

Monitored ions\(^3\):

\(m/z\) 769 (salinomycin)

\(m/z\) 891 (semduramicin)

\(m/z\) 783 (narasin A)

\(m/z\) 688 (monensin A)

\(m/z\) 608 (lasalocid)

Calculation. Calculate the peak height or peak area from the obtained selected ion detection chromatogram\(^4\) to prepare a calibration curve, and estimate the amount of each antibiotic in the sample solution\(^4\).

Note 1. Prepared by drying a suitable amount under reduced pressure (not exceeding 0.67 kPa) at 60°C for 3 hours

2. Gemini 5µ C18 110A (Phenomenex; the retention times of salinomycin, semduramicin, narasin A, monensin A and lasalocid are approximately 9, 6, 13, 8 and 4 minutes, respectively, under the operating conditions of this method) or an equivalent

3. Operating conditions for LCMS-2010EV (Shimadzu)

4. For narasin, the calculated amount of narasin A shall be regarded as the amount of narasin. For monensin, the calculated amount of monensin A shall be regarded as the amount of monensin sodium.

«Summary of analysis method»

This method is intended to determine the amounts of SL, SD, NR, MN and LS in a feed at the same time by liquid chromatography-mass spectrometry using electrospray ionization (ESI) (positive ion mode) using a sample solution prepared by extracting with acetonitrile, purifying through a silica gel minicolumn, and dissolving in methanol.

The flow sheet of this method is shown in Figure 9.3.4-1.
10.0 g of the sample
- Add 100 mL of acetonitrile and stir for 30 min.
- Filter (through filter paper No.5A).
- Collect 25 mL of the filtrate.
- Condense under reduced pressure (at 40°C or lower) and evaporate into dryness (with nitrogen gas).
- Add 10 mL of hexane-ethyl acetate (9:1).

Sep-Pak Plus Silica cartridge (previously washed with 10 mL of hexane).
- Place on the minicolumn a funnel containing approximately 20 g of sodium sulfate (anhydrous).
- Load the sample solution.
- Wash with 5 mL of hexane-ethyl acetate (9:1) (3 times).
- Wash the sodium sulfate (anhydrous) with 5 mL of hexane-ethyl acetate (9:1).
- Wash the silica gel minicolumn with 10 mL of hexane-ethyl acetate (9:1).
- Elute with 15 mL of hexane-ethanol (4:1).
- Condense under reduced pressure (at 40°C or lower) and evaporate into dryness (with nitrogen gas).
- Add 10 mL of methanol.
- Centrifuge at a high speed (at 5,000×g for 5 min).

LC-MS

### Notes and precautions

[1] For the definition etc. of each working standard, refer to «Notes and precautions» [9] in Section 1, 1 of this Chapter.

[2] It is recommended to stuff a small amount of absorbent cotton at the top of the funnel stem on which to place sodium sulfate (anhydrous). Alternatively, a reservoir with an appropriate frit packed with sodium sulfate (anhydrous) is applicable.

[3] Ammonium adduct ion [M+NH₄]⁺ of each antibiotic shall be used as monitored ions. The mass spectra for salinomycin, semduramicin, narasin A, monensin A and lasalocid are shown in Figure 9.3.4-2.

Under the example operating conditions mentioned above, fragment ions were detected other than the monitored ions of interest for each antibiotic. It is therefore necessary to confirm in advance the possible production of these fragment ions and their charge/mass ratios, as they can differ depending on the operating conditions and the type of the liquid chromatograph-mass spectrometer. Typical fragment ions produced under the operating conditions of this test include m/z 734, 629, 748, 635 (or 618) and 573 (or 555) for salinomycin, semduramicin, narasin A, monensin A and lasalocid, respectively.

When these antibiotics are detected by this test method, it is recommended not only to quantify by monitoring the ions of interest but to confirm that the same fragment ions are detected in the sample solution as in the standard solutions under the operating conditions employed.
Figure 9.3.4-2 Mass spectrum for each antibiotic

[4] Example selected ion detection (SIM) chromatograms obtained from a mixed standard solution and sample solution are shown in Figure 9.3.4-3.

Figure 9.3.4-3 SIM chromatograms for the mixed standard solution and sample solution

Mixed standard solution (equivalent to 0.6 ng (potency))

Adult chicken grower formula feed (equivalent to 0.5 g (potency)/t)
4 Identification test method - Identification test method for polyether antibiotics by microbioautography

4.1 Premix

Antibiotics of interest: SL, MN and LS

Scope of application: Feed

A. Reagent preparation

1) Salinomycin standard solution. Dry a suitable amount of salinomycin working standard under reduced pressure (not exceeding 0.67 kPa) at 60°C for 3 hours, weigh accurately not less than 40 mg, add methanol and dissolve to prepare a salinomycin standard stock solution with a concentration of 1 mg (potency)/mL.

At the time of use, accurately dilute a quantity of the standard stock solution with methanol to prepare a standard solution with a concentration of 10 µg (potency)/mL[j]

2) Monensin standard solution. Weigh accurately not less than 40 mg of monensin working standard, add methanol and dissolve to prepare a monensin standard stock solution with a concentration of 1 mg (potency)/mL.

At the time of use, accurately dilute a quantity of the standard stock solution with methanol to prepare a standard solution with a concentration of 10 µg (potency)/mL[j]

3) Lasalocid standard solution. Weigh accurately not less than 40 mg of lasalocid working standard, add methanol and dissolve to prepare a lasalocid standard stock solution with a concentration of 1 mg (potency)/mL.

At the time of use, accurately dilute a quantity of the standard stock solution with methanol to prepare a standard solution with a concentration of 10 µg (potency)/mL[j]

4) Culture medium: Medium F-22

5) Pore suspension and amount of addition. Use Bacillus subtilis ATCC 6633 as the test organism. Add about 0.2 mL of a pore suspension with a concentration of 1×10⁷ pores/mL per 100 mL of the culture medium.

6) Extraction solvent. A mixture of methanol and water (9:1) (use methanol in the case of LS.)

7) Developing solvent. A mixture of ethyl acetate, hexane, acetone, and methanol (20:8:1:1)

8) Chromogenic substrate. Dissolve 100 mg of 3·(4-iodophenyl)-2·(4-nitrophenyl)-5-phenyltetrazolium chloride in water to make 200 mL.

B. Preparation of sample solution

Weigh accurately 3 to 5 g of the analysis sample, place in a 200-mL stoppered Erlenmeyer flask, add 100 mL of the extraction solvent, extract with stirring for 20 minutes, and filter the extract through filter paper (No.5A).

Accurately dilute a quantity of the filtrate with the extraction solvent to prepare a sample solution with a concentration of 10 µg (potency)/mL.

C. Identification
Proceed as directed in the Thin-layer chromatography, Preparation of agar plates, Incubation, and Identification in Section 1, 2-C except for the following procedures.

Use a thin-layer plate made of silica gel\textsuperscript{Note 1}, spot 25 µL each of the standard solution and sample solution, and develop until the ascending front of the developing solvent reaches the top of the thin-layer plate.

Note 1. Use a TLC Plate Silica Gel 60 (20×20 cm) (Merck) or an equivalent after drying at 110°C for 2 hours.

«Summary of analysis method»

This method is intended to identify AL, MN and LS in a premix by microbioautography using a sample solution prepared for quantification.

The flow sheet of this method is shown in Figure 9.3.5-1.

Sample (3.0-5.0 g)

Extract with 100 mL of methanol-water (9:1) (use methanol in the case of LS) (with a magnetic stirrer for 20 min).

Dilute a quantity of the filtrate with methanol-water (9:1) (use methanol in the case of LS) to prepare the sample solution (10 µg (potency)/mL).

Spot on a thin-layer plate (25 µL).

Develop.

Prepare agar plates (allow to stand at 10-20°C for 3 hr).

Incubate (at 35-37°C for 16-24 hr).

Determine the Rf value.

Figure 9.3.5-1 Identification test method for SL, MN and LS (premix)

History in the Feed Analysis Standards [18] New

«Notes and precautions»

[1] For the method of preparation for the standard solution, refer to «Notes and precautions» [8] in Section 1, 1 of this Chapter.

An example method of preparation for the standard solution is shown in Table 9.3.5-1.

5 Control test method - Rapid quantitative method

5.1 Absorption spectrometry (chicken feed)

[58 Chiku B No.1676, notified by the Head of the Livestock Industry, Ministry of Agriculture, Forestry and Fisheries, as of July 6, 1983]

1. Reagents and reagent preparation
   (1) Methanol (guaranteed grade)
   (2) Diethyl ether (guaranteed grade)
   (3) Sodium hydroxide (guaranteed grade)
   (4) Ethyl acetate (guaranteed grade)
   (5) p-Nitrobenzene diazonium fluoroborate solution. Dissolve 50 mg of p-nitrobenzene diazonium fluoroborate in water to make 100 mL (prepare at the time of use).
   (6) Lasalocid sodium standard solution. Weigh accurately 40 mg of lasalocid sodium working standard (potency), place in a 100-mL volumetric flask, add methanol to dissolve, and further add methanol up to the marked line to prepare a lasalocid sodium standard stock solution (1 mL of this solution contains 400 µg (potency) of lasalocid sodium).

   At the time of use, dilute the stock solution exactly 10-fold with methanol to prepare a lasalocid sodium standard solution\(^\text{Note}^1\) (1 mL of this solution contains 40 µg (potency) of lasalocid sodium).

2. Quantification\(^\text{Note}^2\)

Extraction. Weigh accurately 10 g of the analysis sample, place in a 100-mL stoppered Erlenmeyer flask, add accurately 30 mL of diethyl ether\(^\text{Note}^3\), stir for 10 minutes with a magnetic stirrer, allow to stand for 5 minutes, filter the supernatant liquid under pressure\(^\text{Note}^4\), and use the filtrate as the sample solution.

Development and measurement. Immediately transfer exactly 4 mL of the sample solution\(^\text{Note}^5\) to a 10-mL stoppered test tube, evaporate into dryness in a water bath at 50°C \(^\text{Note}^6\), add accurately 6 mL of methanol, shake for 1 minute\(^\text{Note}^7\), and filter through dry filter paper\(^\text{Note}^8\). Transfer exactly 3 mL of the filtrate to a 10-mL stoppered test tube, dissolve under ice-cooling, add exactly 1 mL of p-nitrobenzene diazonium fluoroborate and exactly 1 mL of 4% sodium hydroxide solution, and determine the
absorbance at a wavelength of 560 nm using methanol as the blank.\(^{[1]}\) Note 9.

Preparation of calibration curve.\(^{[10]}\) Weigh accurately 20 g of a lasalocid sodium-unsiked sample (with the same composition as the analysis sample except for the absence of lasalocid sodium), place in a 100-mL stoppered Erlenmeyer flask, add accurately 60 mL of diethyl ether,\(^{[11]}\) stir for 10 minutes with a magnetic stirrer, allow to stand for 5 minutes, and filter the supernatant liquid by injection under pressure.\(^{[4]}\) Transfer exactly 4 mL of the filtrate to each of 10-mL stoppered test tubes A, B, C, D and E, and evaporate into dryness in a water bath at 50°C.\(^{[6]}\) To the respective test tubes add 0, 1, 2, 3 and 4 mL of the lasalocid sodium standard solution,\(^{[13]}\) further add methanol to make exactly 6 mL in each tube,\(^{[14]}\) shake for 1 minute,\(^{[7]}\) and filter through dry filter paper.\(^{[8]}\) Then proceed in the same manner as described for the sample solution and determine the absorbance to prepare the calibration curve.

Calculation. Calculate the amount of lasalocid sodium in the sample solution from the calibration curve and estimate the amount of lasalocid sodium in the sample according to the following equation.

\[
\text{Amount (g (potency)/t) of lasalocid sodium in the sample} = L \times \frac{30}{W} \times \frac{1}{4}
\]

\(L\): Amount (µg (potency)) of lasalocid sodium in the sample calculated from the calibration curve

\(W\): Weight (g) of the sample used for analysis (g)

Note 1. The standard solution can be stored for about 1 week in a refrigerator.

2. Avoid direct sunlight during quantification.

3. Ethyl acetate can be used in lieu of diethyl ether.

4. Cut out a piece of Toyo filter paper No.6 or an equivalent and set it in a membrane filter holder equipped with a syringe etc.

   Instead of filtering by injection under pressure, it is permissible to transfer the extract to a stoppered centrifuge tube and centrifuge (at 3,000 rpm for 5 minutes). When using ether, care should be taken not to catch fire.

5. When using ethyl acetate, the amount of the sample solution shall be 2 mL, and the amount of methyl alcohol after evaporating into dryness shall be 3 mL. The filtration procedure can be skipped to proceed to the step of cooling in ice.

6. Evaporation shall be performed with a ventilation system, such as draft chamber. Care should be taken not to catch fire. When using ethyl acetate, evaporate the sample solution into dryness in a water bath at 90°C or higher. When the sample is rich in fat, it can evaporate into a tarry mass but not into dryness, which however, is acceptable as long as there is no ether (ethyl acetate) odor left.

7. Shake vigorously with the hand. It is permissible to shake in a shaker or an ultraviolet washer.

   Undissolved residues can be left on the test tube wall, but do not affect the quantification.

8. Use Toyo filter paper No.6 or an equivalent.

9. Determine the absorbance within 1 hour after development.

10. When proceeding under the same conditions (standard solution, evaporating temperature, time...
of operation, etc.), the slope of the calibration curve is not affected but the blank value is affected by the composition of raw materials of feed. As long as the test is performed under the same conditions, therefore, a previously prepared calibration curve can be used after correcting for the blank value (absorbance of the sample solution — absorbance of the unspiked feed).

11. Use ethyl acetate if ethyl acetate is used in Note 3.
12. When using ethyl acetate, the amount shall be 2 mL.
13. When using ethyl acetate, the amounts shall be 0, 0.5, 1.0, 1.5 and 2.0 mL, respectively.
14. When using ethyl acetate, the amount shall be 3 mL.
15. When using ethyl acetate, this process can be skipped.

«Summary of analysis method»

This method is intended to determine the absorbance of LS in a feed at a wavelength of 560 nm using a sample solution prepared by extracting with diethyl ether, changing the solvent to methanol, and developing with p-nitrobenzene diazonium fluoroborate.

The flow sheet of this method is shown in Figure 9.2.28-11.

![Flow sheet of rapid quantitative method for lasalocid sodium in feed (ether extraction method)](image-url)

Note: p-Nitrobensene diazonium fluoroborate solution

Figure 9.2.28-11 Flow sheet of rapid quantitative method for lasalocid sodium in feed (ether extraction method)

«Notes and precautions»
[1] After development, allow the sample solution to stand for 5 to 10 minutes before determining the absorbance.

5.2 Liquid chromatography (chicken feed and cattle feed (including pellets))
[3 Chiku B No.1113, notified by the Head of the Livestock Industry Bureau, Ministry of Agriculture, Forestry and Fisheries, as of June 3, 1991]

1. instruments and equipments
   (1) Stoppered Erlenmeyer flask
   (2) Volumetric flask
   (3) Pipette
   (4) Volumetric cylinder
   (5) Microsyringe
   (6) Magnetic stirrer
   (7) Water bath
   (8) High-performance liquid chromatograph

2. Reagents
   (1) Methanol (guaranteed grade)
   (2) Monophosphate dihydrogen phosphate (guaranteed grade)
   (3) Phosphoric acid (guaranteed grade)
   (4) Takadiastase. An enzyme obtained by the extraction and purification of a cultured filtrate of Aspergillus oryzae, mainly containing amylase, a digestive enzyme for carbohydrate.
   (5) Lasalocid sodium standard for feed analysis

3. Preparation of reagents
   (1) Lasalocid sodium working standard solution
      Weigh accurately 50 mg (potency) of lasalocid sodium standard, place in a 100-mL volumetric flask, add methanol to dissolve, further add methanol up to the marked line to prepare a lasalocid sodium standard stock solution (1 mL of this solution contains lasalocid sodium 500 µg (potency)).
      At the time of use, accurately dilute this stock solution with methanol to prepare lasalocid sodium standard solutions containing amounts equivalent to 2, 4 and 6 µg (potency)/mL in the case of cattle feed, or amounts equivalent to 6, 8 and 10 µg (potency)/mL in the case of chicken feed¹
   (2) Enzyme solution¹
      Dissolve 2.5 of of takadiastase in water to make 100 mL.

4 Quantification
   (1) Extraction¹
      Weigh 10 g of the analysis sample, place in a 200-mL stoppered Erlenmeyer flask, add 20 mL
of the enzyme solution, mix thoroughly, and allow to stand in a water bath at 40°C for 20 minutes. Then, add 80 mL of methanol, stir for 10 minutes with a magnetic stirrer, filter the supernatant liquid through membrane filter (pore size not exceeding 0.5 µm), and use the filtrate as the sample solution.

(2) High-performance liquid chromatography

Inject 20 µL each of the sample solution and lasalocid sodium standard solutions into a high-performance liquid chromatograph using a microsyringe to obtain chromatograms\(^\text{(1)}\).

Example operating conditions\(^\text{Note 3}\)

Detector: Fluorescence detector (excitation wavelength: 310 nm, emission wavelength: 419 nm)

Column: A stainless steel tube 4.6 mm in internal diameter and 250 mm in length, packed with octadecylsilanized silica gel 5 µm in particle size.

Eluent: A mixture of methanol and 10 mmol/L monophosphate dihydrogen phosphate solution (adjust the pH to 2.1 with phosphoric acid) (9:1)

Flow rate: 1.0 mL per minute

(3) Calculation

Calculate the amount of lasalocid sodium in the sample according to the following equation.

\[
\frac{A}{2} = \frac{\text{Amount (g (potency/t) of lasalocid sodium in the sample)}}{A}
\]

\(A\): Weight (ng (potency)) of lasalocid sodium calculated from the calibration curve

Note 1. When it is difficult to dissolve, apply ultrasonic waves.

2. In the case of powder feed, the expression “add 20 mL of the enzyme solution, mix thoroughly, and allow to stand in a water bath at 40°C for 20 minutes. Then, add 80 mL of methanol” shall be replaced with “add 100 mL of methanol”.

3. The methanol used as eluent shall be a regent for high-performance liquid chromatography or an equivalent.

«Summary of analysis method»

This method is intended to determine the amount of LS in a chicken feed or cattle feed (including pellets) by liquid chromatography equipped with a fluorescence detector using a sample solution prepared by extraction.

The flow sheet of this method is shown in Figure 9.2.28.12.
10 g of the analysis sample
Add 20 mL of enzyme solution and allow to stand at 40°C for 20 min.
Add 80 mL of methanol and extract (with a magnetic stirrer for 10 min).
Supernatant liquid.
Filter through membrane filter (pore size not exceeding 0.5 µm).
LC-FL (Ex: 310 nm, Em: 419 nm)

Figure 9.2.28-12 Rapid quantitative method for lasalocid sodium in a feed

(6) Chloroform (guaranteed grade)
(7) Potassium hydroxide (guaranteed grade)
(8) Silica gel cartridge

(9) Takadiastase. An enzyme obtained by extraction and purification of a culture filtrate of *Aspergillus oryzae*, mainly containing amylase, a digestive enzyme for carbohydrate. It is a hygroscopic light-yellow powder.

(10) *p*-Nitrobenzenediazonium fluoroborate

(11) Lasalocid working standard

(12) Nitrogen gas

3. Preparation of reagents

(1) Lasalocid sodium standard solution. Weigh 100 mg (potency) of lasalocid standard, place in a 100-mL volumetric flask, add ethanol up to the marked line and dissolve to prepare a lasalocid sodium standard stock solution\(^1\) (1 mL of this solution contains lasalocid sodium equivalent to 1 mg (potency)).

At the time of use, accurately dilute this stock solution with anhydrous ethanol to prepare lasalocid sodium standard solutions containing amounts equivalent to 5, 10 and 15 µg (potency)/mL as lasalocid sodium.

(2) Enzyme solution. Dissolve 4 g of takadiastase in 100 mL of water. Prepare at the time of use.

(3) *p*-Nitrobenzenediazonium fluoroborate solution. Dissolve 50 mg of *p*-nitrobenzenediazonium fluoroborate in 100 mL of water. Prepare at the time of use.

4. Quantification

(1) Extraction

Weigh 15 g of the analysis sample, place in a 200-mL stoppered Erlenmeyer flask, add 15 mL of the enzyme solution, mix thoroughly, and allow to stand in a water bath at 40°C for 20 minutes. Then, add 85 mL of acetonitrile, stir for 30 minutes with a magnetic stirrer, and filter the supernatant liquid through filter paper (No.5A). Transfer exactly 50 mL of the filtrate to a 300-mL separating funnel, add 50 mL of water, mix, add 100 mL of hexane, shake for 10 minutes, allow to stand, and transfer the hexane phase (upper phase) to a 300-mL recovery flask. Add 100 mL of hexane to the
separating funnel, shake for 1 to 2 minutes, allow to stand, and transfer the hexane phase to the recovery flask. Evaporate this solution into dryness under reduced pressure in a water bath at approximately 50°C. Add 10 mL of hexane to dissolve the residue and use as the sample solution subject to cartridge column chromatography.

(2) Cartridge column chromatography

Connect a silica gel cartridge with a syringe and wash with 10 mL of hexane. Transfer the sample solution to the syringe, wash the recovery flask with 2 to 3 mL of hexane, and transfer the washings to the syringe. Further, repeat this washing procedure 2 times, allow to flow down until the amount is 1 mL or less, and add 30 mL of chloroform to wash the syringe. Place a 50-mL stoppered centrifuge tube under the silica gel cartridge, and elute lasalocid sodium with 10 mL of a mixture of acetone and methanol (4:1). Evaporate the eluate into dryness with nitrogen gas in a water bath at 50°C, to the residue add exactly 20 mL of anhydrous ethanol, dissolve with ultrasonic waves for 1 minutes, and use as the sample solution.

(3) Development

Transfer exactly 4 mL of the sample solution to a 25- to 30-mL stoppered test tube, add accurately 6 mL of anhydrous ethanol, mix, allow to cool in an ice water bath for 5 minutes, add accurately 1 mL of p-nitrobenzenediazonium fluoroborate solution, and mix. Allow the stoppered test tube to stand in an ice water bath for 10 minutes, add 1 mL of sodium hydroxide (4 w/v%) solution, mix, and develop. Allow the stoppered test tube to return to room temperature and determine the absorbance at the wavelength of maximum absorption of about 560 nm, using anhydrous ethanol as the blank.

(4) Preparation of calibration curve

Proceed as described in (1) and (2) with 15 g of a lasalocid sodium-unspiked sample (with the same composition as the analysis sample except for the absence of lasalocid sodium) to prepare an unspiked sample solution.

Transfer exactly 4 mL of the unspiked sample solution to each of 25- to 30-mL stoppered test tubes A, B, C and D. Add 6 mL each of the lasalocid standard solutions with concentrations of 5, 10, 15 µg (potency)/mL or anhydrous ethanol to the stoppered test tubes, develop as directed in (3), and determine the absorbance to prepare the calibration curve.

(5) Calculation

Calculate the concentration of lasalocid sodium in the sample solution from the calibration curve, and estimate the amount of lasalocid sodium in the sample according to the following equation.

\[ \text{Amount} \left( \text{g (potency)/l} \right) = A \times 4 \]

where:

- \( A \) = Concentration (µg (potency)/mL) of lasalocid sodium in the sample solution calculated from the calibration curve.

Note 1. Use a Sep-Pak Plus Silica cartridge (Waters) or an equivalent.

2. Inject under pressure at a rate of 2 to 3 mL/min.
Summary of analysis method

This method is intended to determine the absorbance of LS in a feed (mainly pellet feed for cattle) at a wavelength of 560 nm using a sample solution prepared by extracting with an enzyme solution and acetonitrile, changing the solvent to hexane, purifying through a silica gel minicolumn, and developing by diazotization.

The flow sheet of this method is shown in Figure 9.2.28-14.

- 15 g of the sample
  - Add 15 mL of enzyme solution and mix.
  - Allow to stand at 40°C for 20 min.
  - Add 85 mL of acetonitrile and stir for 30 min.
  - Filter (through filter paper No.5A).
- Collect 50 mL of filtrate (into a 300-mL separating funnel)
  - Add 50 mL of water and mix.
  - Add 100 mL of hexane and shake for 10 min.
- Collect into a 300-mL recovery flask.
- Sep-Pak Silica cartridge (previously washed with 10 mL of hexane).
  - Wash the round-bottom flask with 2-3 mL of hexane 3 times.
  - Wash with 30 mL of chloroform.
  - Elute with 10 mL of acetone-methanol (4:1).
- 50-mL centrifuge tube
  - Evaporate into dryness with nitrogen gas (50°C)
  - Dissolve the residue with 20 mL of ethanol (with ultrasonic waves for approximately 1 min).
- Sample solution
Spiked sample solution

- 4 mL (test tube)
- 6 mL of ethanol
- Mix.
- Allow to stand in a cold water bath (at 2-4°C for 5 min).
- Add 1 mL of diazotization solution Note and mix
- Allow to stand in a cold water bath (at 2-4°C for 10 min).
- Add 1 mL of 4% NaOH solution and mix.
- Allow to return to room temperature
- Determine absorbance (at 560 nm).

Unspiked sample solution

- 4 mL (test tube A) 4 mL (test tube B) 4 mL (test tube C) 4 mL (test tube D)
- 6 mL of ethanol Standard solution Standard solution

Figure 9.2.28-14 Rapid quantitative method for lasalocid sodium

«Notes and precautions»

[1] The standard stock solution is stable for approximately 3 when stored at 4°C.
[2] An example calibration curve for lasalocid sodium is shown in Figure 9.2.28-15.
